Suicide in Ireland and in other EU countries, Rates per 100,000 – All ages

Data for 2004-2008 - WHO-EuroStat
Suicide death rate by both genders, standardised in Europe per 100,000 inhabitants

WHO-EuroStat
Suicide rate per 100,000 of 15-24 year-olds in Ireland and in other EU countries

Data for 2004-2008 - WHO-EuroStat
Suicide death rate for 15-19 year old males in Europe, crude death rate per 100,000 persons

WHO-EuroStat
Suicide death rate for 15-19 year old females in Europe, crude death rate per 100,000 persons

Data for 2010

WHO-EuroStat
Background

- Financial crisis and global economic recession in 2008
- Ireland has been profoundly affected
- Unemployment levels in Ireland grew from 4% in 2007 to a peak of 15% in early 2012
- In 2012, Ireland had the highest emigration rate and was the 4th most indebted of the 27 EU Member States (Eurostat)
Background

- Studies have shown that economic recession generally increases suicide

- Analysis of 54 countries showed an excess in 2009 of 4,884 suicides compared to the number expected if the trend in 2000-2007 had continued

- Over the three years 2008-2010 studies found an excess of 680 suicides in Spain, 1,000 suicides in England and 4,750 suicides in the US

- The impact of recession on non-fatal suicidal behaviour has not been well established

- Ireland’s National Registry of Deliberate Self Harm provides a unique opportunity to assess the recession’s impact at a national level on a well-defined form of medically-serious suicidal behaviour
Aims

To assess the impact of economic recession and austerity in Ireland over the five years 2008-2012 on national rates of both suicide and self harm.
Setting and data

- **500 Suicide deaths per annum**
- **12,000 Hospital-treated deliberate self-harm presentations per annum**

**Central Statistics Office**
- 1980-2012

**National Registry of Deliberate Self-Harm**
- 2003-2012

Pop. 4,585,500 (2011 census, CSO)
Analysis

Step 1: Joinpoint analysis of suicide rates 1980-2012

  - Tests for change in level and trend
  - Used quarter 1 (or January) of 2008 as the advent of the recession
  - Adjusted for serial autocorrelation and seasonality

Step 3: Estimated the excess number of suicide deaths and self-harm presentations
  - Assuming the pre-recession trend continued
  - Assuming the pre-recession trend levelled-off
Joinpoint analysis of Irish suicide

![Graph showing suicide rates per 100,000 for males and females from 1980 to 2012. The graph indicates a general increase in suicide rates for males, with a peak around 1998, followed by a decline. Female suicide rates remain relatively stable throughout the period.]
Trend in quarterly male (left) and female (right) suicide (2000-2012)

- Excess: 476 deaths
- Observed rate
- Post-recession trend
- Trend levelled off
- Pre-recession trend

Excess: 85 deaths
- Observed rate
- Post-recession trend
- Trend levelled off
- Pre-recession trend
Trend in monthly male (left) and female (right) self harm presentations to hospital (2004-2012)
Estimated impact of the economic recession and subsequent austerity on suicide and self harm in Ireland, 2008-2012

Note: * p<0.05, ** p<0.01, *** p<0.001; Recession arrived in January 2008; Dependent variables were the age-standardised rate of quarterly suicide and of monthly self harm presentations to hospital per 100,000 >15 years.
Age-specific impact

- The 25-44 year-old male suicide rate was twice what it would have been (104% higher) if the pre-recession trend continued with an associated excess of 336 deaths (95% CI=179 to 493, P<0.001).
- The 45-64 year-old male suicide rate was 72% higher and there was an excess of 185 deaths (95% CI=67 to 304, P=0.003).
- The significant impact on male self harm was also most evident in these age groups with 3064 (95% CI=644 to 5484, P=0.014) and 881 (95% CI=156 to 1605, P=0.018) excess self harm presentations by 25-44 and 45-64 year-old men, respectively.
- The recession’s impact on female suicidal behaviour was confined to self harm among 15-24 year-olds for whom there were 1398 (95% CI=122 to 2675, P=0.032) more presentations to hospital than if pre-recession trends had persisted.
Summary

- The study provides compelling evidence that the profound economic recession from which Ireland is now emerging has led to increased suicide mortality in men and increased non-fatal suicidal behaviour by men and women.

- This provides a stark reminder of the tragic human costs of policy failure in economic management by governments and other institutions at national and international level.

- The findings also highlight the need for reliable and well-standardised data on suicide, self harm and determinants of suicidal behaviour in the population to guide policy on how best to mitigate the effects of economic crises on mental health and wellbeing.
Trends in rates of self-harm and suicide in Ireland

**Trends in rates of suicide**

- Men: +9%
- Women: -7%
- All: +5%
